ABSTRACT

In the event of climate change, sheltered agriculture might offer plenty of opportunity for high-value vegetable crop production to occur during the "off" season. Tomato ($Solanum\ lycopersicum\ L$.) is one of the most significant high-value crops and a rich source of lycopene, β -carotene, phenols, flavonoids, and several vitamins. Growers can produce tomato fruit during the off-season and get higher prices in the market by using protected buildings like net houses, polyhouses, semi-high tunnels, and mulching. Through the modification of the natural environment, this technology has significantly improved productivity for areas with unfavourable weather conditions. In addition, it has

extended the harvest period, increased yields, improved quality, increased production stability, and made fresh, high-quality produce available during the off-season, especially in Himalayan areas. From this study, it is pertinent to opine that tomato is high value vegetable crop in which protected cultivation is always advantage over open field cultivation. We highlight or briefly discussed the differences between growing tomatoes in an open field and under protection structure, as well as the growth characteristics, yield, and other quality parameters in this review.

Keywords: Tomato; Solanum lycopersicum; protected cultivation; open field condition; yield.

1. INTRODUCTION

Tomato (Solanum lycopersicum L.) is one of the most widely-grown greenhouse vegetables in the world [1], and is highly demanded by fresh market. It plays a vital role in human health also [2]. "Fresh tomato production was around 180 million tonnes worldwide in 2020. The top five tomato-producing nations are China, India, Pakistan, Turkey, and the United States, together generating more than 60% of the world's tomatoes. China is the country with the largest tomato production in the world, with an annual output of more than 65.15 million tonnes, accounting for one-third of the global tomato production" [3]. "It's output in India reached a peak in 2019-20 at 21.187 million tonnes (MT), and it has subsequently been in decline. It decreased to 20.69MT in 2021-2022 and 20.62MT in 2022-2023" [4]. "Tomatoes are high in vitamin C, potassium, folate, and vitamin K, all of which are responsible for a variety of health benefits, including cancer prevention, heart health, and constipation prevention" [5], [6], [7]. "Furthermore. tomatoes have significant nutritional value and positive health impacts due to their potassium, ascorbic acid (Vitamin C), and lycopene levels. Tomato continues to be the most important vegetable in the world due to increasing commercial and dietary value, widespread production as well as model plant for research purpose" [8]. Similarly, tomato is utilized as a fresh crop or processed into various forms such as paste, puree and juices.

"Tomatoes are planted both in the greenhouse and open fields. Therefore, developing a sustainable production system is essential for improved crop growth and a consistently high tomato yield" [3]. "In the plains of India, tomato is mainly grown as Rabi crop. However, in the Himalayan region, it is mostly grown as summer season crop. In in trans-Himalayan region of Ladakh its production is limited due to harsh climate, short growing season and extreme temperature fluctuations. Hence, protected cultivation is a feasible answer for successful

cultivation of tomato in this region" [9]. "With the innovative technique of protected cultivation, environmental conditions can be partially or completely controlled" [10], [11], [12]. Singh and Asrey [13] "recommended that cultivation of tomato in a greenhouse would help to obtain high productivity and better return. The greenhouse environment encompasses climatic nutritional elements, along with structural and mechanical conditions". "If properly managed, it can significantly increase fruit quality and yield. Since the costs associated with greenhouse cultivation are generally higher, due to the initial investments in the structure" [14]. The protected cultivation of tomato is always aimed to obtain high yield, good quality crop, improved shelf life and year around availability of tomato fruit [15], "The parameters of economic importance like fruit weight and yield are better under protected conditions but the nutritional parameters like vitamin C and lycopene content are higher in open conditions" [18]. "Cultivation of tomatoes under protected structure protects tomato fruit from biotic and abiotic stresses especially, during the off-season. Also increases yield by increasing fruits per plant, fruit weight, fruit length and fruit diameter" [19], [15]. "Under protected structures such as net houses and polyhouses, growers can produce tomato fruit during the off-season and receives higher prices in the market. If these structures are carefully maintained, it will increase productivity and net returns per unit area, and also keep pests away" [20]. Rana et al. [18] "also observed that tomato extensively in the grown productivity". "The greenhouses increase environmental factors affecting greenhouse tomato include air and root-zone temperatures, relative humidity (RH), light conditions (L), disease and insect intervention, as well as carbon dioxide" [21]. "Microclimatic parameters are directly affected the fruit yield and quality of tomato" [22], [14]. "Different techniques and methods of determinant and indeterminate varieties of tomato planting under open-field and greenhouse conditions are available in the textbooks" of [23], [24], [25], [21].

The main obstacles to growing vegetables particularly tomato is climate change, shrinking agricultural land, water shortages, rising seed and input costs, a lack of qualified labour, market price volatility, the appearance of illnesses and insect resurgence, etc. In order to support the protected production of tomatoes and to recommend various scholars for upcoming research and development, this review paper has been painstakingly documented.

2. PERFORMANCE OF TOMATO UNDER PROTECTED CULTIVATION AS COMPARE TO OPEN FIELD CULTIVATION

Protected cultivation of vegetables endorses effective use of the soil nutrients, soil moisture, humidity, temperature, CO2, light intensity etc., which results in increase the production and quality vegetables by delimiting biotic and abiotic stresses whereas in open cultivation plants suffer a great damage due to weeds, insects and diseases with limited use efficiency of natural resources and environment factors. Greenhouse is the present trends in Indian agriculture where the crop is raised under fully automated or partly artificially manipulated environment endorse higher production and productivity as compared to open filed cultivation [11]. Takteet et al. [26] revealed that polythene sheet and shading nets avoids extreme sunshine, chilling, freezing, high wind and biotic stresses. Environmental factors like day and night temperature, air relative humidity, light intensity, light period, CO₂ concentration. water availability, availability, plant population, plant media etc. are significantly maintained in greenhouse for crop cultivation [10], [18]. There is drastic increase in the resource-use efficiency through protected crop cultivation in comparison to the conventional open field cultivation [27]. Tomato production has undergone many changes in the way as it is being grown in different regions, since different limiting factors including climatic conditions, availability of water and nutrients, and quality and quantity of light must be taken into account to provide appropriate conditions for the optimal growth and development of the crop. Because of their sophisticated light-perception system, plants are able to modify and optimize their metabolism and performance in response to the specific environmental factors that are most common. As observed by Arsovski et al. [28], that light affects developmental and physiological processes which include germination [29], flowering [30] and direction of growth [31]. The

arowina conditions especially liaht temperature are also known to influence both composition and quality of tomato fruits. [32] "reported that plant height is better in polyhouses as compared to open field conditions". "The environment in the polyhouse favour the growth and development of tomato plant through increased plant height, number of branches, stem grith and yield" [33], [34], [18]. "However, fruits harvested from open field had higher TSS, acidity, total sugar, ascorbic acid and the lycopene content than the fruits grown under protected conditions" [35], [18]. "Therefore, both types of environmental conditions are favourable in some aspects. Protected cultivation had a significant impact in improving the crop productivity, employment and income generation. Furthermore, protected cultivation attains more stable income than open field cultivation" [36], [37], [38], [39]. Therefore, it is necessary to grow tomatoes in protected environments like net houses, poly houses, and green houses, among others, in order to acquire high-quality produce and production throughout the off-season. Green houses have a great deal of potential to increase tomato yield [40], [41].

3. PERFORMANCE OF CAPSICUM FOR VEGETATIVE GROWTH PARA-METERS

"An appropriate environmental condition inside polyhouse promotes robust cell division and cell enlargement in the terminal portion of the plant, which supports the maximum plant height, the greater number of leaves per plant, a greater number of branches per plant, and overall plant growth. In Tomato, a greater number of branches and better plant height reported in polyhouses as compared to open field conditions" [32], [9]. "Total fruit bearing period was also prolonged under polyhouse. For that reason, total number of fruit harvests was more in polyhouse than open field" [42], [43]. Plant spacing and stem pruning are the two most important factors. Optimum plant spacing may help in proper utilization of land and high-quality fruits. However, stem pruning may influence the production of yield [44]. Suitable day and night temperature, relative humidity and light intensity are available in polyhouse resulting in increasing yield by improving the vegetative characters in tomato [45]. Foolad and Lin [46] attempted to connect tomato vegetative development to cold tolerance during seed germination. discovered that there was no connection between the two and suggested that distinct genes are engaged at these developmental possible. stages. Therefore. it's characteristics that affect fruit output at lower temperatures have little to do with growth during the vegetative stage. Ulukapi et al. [47] reported that the average fruit weight and quality increased with fruit reduction on the stem, and accordingly the plant yield increased. Leaf and side branch pruning has been shown to improve final output in a number of ways. According to Khoshkam et al. [48], "training increases a plant's capacity to absorb sunlight, which is essential for its growth and development. It is also important to maintain adequate air movement around the plant to reduce risk of fungus and insect problems. A dense canopy of leaves shades the fruits, causing them to be pale". Rana et al. [18] "reported that tomato plants grown in polyhouse climate produced about 50% higher fruit yield than the tomato plants grown in open field conditions". "The significantly higher yield in the plants grown under polyhouse condition over the plants grown in the open field was associated with the production of higher number of fruits with greater length and diameter and fruit weight than those in open field" [34], [15].

Dixit et al. [41] "reported that different combinations of organic manures i.e., FYM, Vermicompost and Poultry manure are the best treatment for better plant growth and flowering of tomato under protected structure". Reddy et al. [49], Patil et al. [50], Poul et al. [51] "also reported that organic manure increase plant growth and yield". "The use of FYM was found to be the most important variable and showed a significantly positive relationship with the yield of tomato under-protected and open-field conditions as reported" by [39].

4. PERFORMANCE OF TOMATO FOR YIELD PARAMETERS

Tomato yield is a function of the entire plant's growth rather than a single feature. A tomato plant will never produce a large amount of yield if it does not grow well. Thus, the relationship between plant form, physiology, and growth circumstances determines yield [23]. "Tomato yield in the tropics is much lower than that in the temperate zone due to several factors like high humidity, high temperature, excessive rainfall, disease and pest" [52]. Temperature has a major impact on crop phenological growth and output [53]. Plants grown in greenhouse have favourable environmental conditions that enable more effective use of water and nutrients,

ensuring that the crop's genetic potential is fully expressed for growth and production. However, decrease in temperature will also affect the growth and development of plant including biomass production, fruit growth and yield [54], [23]. According to Adams et al. [45], "trusses form more quickly at higher temperatures. Because of the shorter fruit growth period and faster initiation of new trusses at higher temperatures, early yields are higher" [55], [45]. "Tomato plant grown under polyhouse was observed to be earlier in flowering and fruit setting by about 3 and 8 days, respectively when compared to the crop raised under open condition" [32]. "Microclimate inside protected structures influences the flowering and fruiting during winter months which is helpful for higher yield in tomato" [56], [34], [15]. Kumar and Arumugam [57] "observed that the growth and vield parameters of different vegetables were significantly enhanced under protected over open field". "Similar results were also observed" by [58]. Parvej et al. [15] "reported that under polyhouse plants had higher number of flower clusters/plant, flowers/cluster, flowers/plant, fruit clusters/plant, fruits/cluster and fruits/plant, and fruit length, fruit diameter, individual fruit weight, fruit weight/plant and fruit yield then open field condition. Kanwar [9] "reported that variety 'Shivalik' performed best with respect to yield followed by 'Pusa Rohini' under polyhouse conditions. Moreover, cultivation of tomato under the polyhouse produced 136.12% more yield per ha and 188.93% more fruits per plant compared to open field cultivation". Khadka and Adhikari [59] "reported that not only yield but also gross return, gross margin and net profit from polyhouse farming of tomato was 60.14%, 68.25%, 74.32% and 69.97% respectively higher than that of open field farming". Kanthaswamy et al. [60], Nagalakshmi et al. [61], Gaikwad et al. [62], Srivastava et al. [63], Mishra et al. [33], Kang and Sidhu [34] "reported that higher values of all the yield components and yield of tomato crop grown under polyhouse was due to the taller plants and much number of branches with greater Leaf area index attributed by warmer "Although lower temperature". amount available PAR (Photosynthetically radiation) under polyhouse could not affect the growth and yield of tomato" [19], [64]. "Overall, to obtain higher yields under this production system, it is important to reduce the elevated temperature and increase the relative humidity inside the protective structures to be adapted for growing conditions. The improved microclimate within the polyhouse, which

included winter temperatures 4-9°C higher than in the adjacent open field, was primarily responsible for the early and higher output of several vegetable crops" [65]. Thus, the polyhouse environment may provide a new scope for commercial production of high value vegetable crops like tomato.

5. PERFORMANCE OF TOMATO FOR QUALITY PARAMETERS

Plants grown in open conditions unfavourable weather and biotic stresses, which leads to lower-quality yield production. In contrast, plants grown in greenhouses yield higher-quality produce because of favourable environmental conditions and lower rates of weeds, diseases, and pests. "Morphological development like plant height, number of branches per tomato plant, leaf area expansion rate and leaf area index were positively favoured due to the warmer environment inside the polvhouse" [66], [67], [42]. "Environmental factors, including light and temperature, may influence and the chemical nutritional composition of tomatoes [68-77], including lycopene, accounting for 80-90% of the total pigments presented in ripened tomato" [78]. Hormonal action is influenced by environmental conditions, which can lead to early blooming, fruit setting, increased fruit production, and increased fruit count. Occurrence of various limiting factors like biotic and abiotic stresses can be minimized under protected structures [17]. Moreover, fruits produced in open field were more acidic (0.49%) than fruits produced in a protected environment (0.40%) [18]. Frusciante et al. [79] "reported that fruit grown open filed condition have higher ascorbic acid rather than fruit grown in protected environment condition. It may be a result of the lower photosynthetic activity of the plant (shading in protected environment) in this environment and lower carbohydrate accumulation in the fruits". Rana et al. [18] "also observed that Genotype influenced the lycopene content of fruit, while the environment did not influence this characteristic". "Cherry tomatoes have also been earlier reported to contain higher content of lycopene than local ones under open conditions" [70].

"Moreover, studies had shown that color shading structures improved tomato fruit quality and carotenoid content" [17]. "Because coloured shade nets enable a better use of the sun's energy due to the modulation of the radiation spectra that reach the crops, thus promoting

physiological responses in plant and fruit development. includina leaf area index. chlorophyll and carotenoid contents, tissue structure, fruit ripening, physiological disorders, nutritional quality, etc" [71]. "In contrast, during tomato production, high temperatures and high solar radiation may reduce lycopene and βcarotene levels resulting in fruit damage, sunscald and increasing unmarketable fruit yield" [72]. Studies also reported that colour net houses provide a positive effect on tomato production in terms of improvement in morphometric parameters like taller plants, larger terminal leaflets compared to those plants grown under open field conditions. According to [16] "tomato varieties grown in open fields and poly houses have varying in flowering time. Phenological development governs the plant growth and productivity". "Days to flowering, fruiting and maturity of crop are the important phenological events which determine the productivity of a crop" [15].

6. CONCLUSION

From this study, it is pertinent to opine that tomato is high value vegetable crop in which protected cultivation is always advantage over open field cultivation. Naturally ventilated greenhouse cultivation endorses maximum plant height, number of leaves, number of branches per plant and overall vegetative growth in tomato. Moreover, Improved yield parameters such as early flowering and fruiting, a greater number of flower and fruits per plant, better fruit set, early fruit ripening, maximum fruit size and weight, early first harvesting, total yield are increased in tomato with superior quality fruit are obtained under polyhouse growing.
